### Notes:

- Use regular Excel® feature to save file with a different name once downloaded from the internet.
- After consulting your last 12 months of your utility bills, please enter monthly kWh and associated charge from the electric company. Note that there can be debt recovery, fuel surcharges, access fees and demand charges on your bill in addition to the charge per kWh. If you have several bills given several meters, please add up charges per month across bills. Room is provided for two meters that are automatically summed in the Combined Meters columns. This allow for meter aggregation.
- Your combined meter information is plotted on a graph and a line is fitted through the data to estimate your monthly fixed charges (access fee, demand charges, etc.) that are expected to remain once the solar panels are installed on the operation. Those charges are shown in column R, row 4 just above the box highlighted in blue.
- You can set the access fee or monthly fixed charge you expect to remain with the solar panels in place to a value of your choice (perhaps an estimated provided by the solar installer or your utility company) or you can set it to zero to accept the estimate from the graph of your electricity bills. If the estimated access fee provided by the tool is negative, please enter \$5 per month. Note that the box will turn green if you choose zero. The green highlighting is intended to showcase that you can modify the cell. Changing the access fee from the computer estimate alters the per unit electricity charge in \$/kWh in column R, row 2. This is important as that per unit electricity charge or variable rate for electricity is used for valuing the electricity generated from the solar panels as net metering is assumed.
- The ZIP code information is there for you to use an National Renewable Energy Lab web-based tool to determine the expected kWh generated per kW of system size to estimate how big a system you would need to build to meet the total kWh you use in a year.
- As of late 2022, the U.S. modified legislation to allow for a 30% federal income tax credit on solar installations. There are provisions for an additional 10% federal income tax credit if the installation site is in a low-income region or on Indian land. Bonus depreciation legislation allows for faster depreciation but is being phased out by 2027, as such the installation year needs to be entered to impact how fast the installation can be depreciation for income tax purposes.
- Use the arrows to go back to the Title page (Start) or move to the next entry screen to set loan details and other information. The Fit to Screen button resizes the pages to fit all information on one screen.

Specifying Panel Productivity, System Expansion, Financing Terms, Use of Tracker Technology, Depreciation method, Electricity rate, Inflation, Federal and State Income Tax rates, Time to realize the federal income tax credit and Opportunity cost of Capital

Please enter input below in the cells highlighted in green. Graphs will update automatically. To ensure proper calculations have been performed, you can also push the 'Refresh' button.

	without tracking	with tracking

Income Tax Rate (State)	5.00%
Years to Use Tax Credit	5
Depreciation	MACRS
Discount rate	6.0%

Notes:

(A) [PVWatts Estimate](#) is a link to a website. Enter your ZIP code in the box (1) shown :

**PVWatts® Calculator**

Get Started:  1 **GO »**

Then click on "Go to System Info" (2)

Now specify the direct current (DC) System size in kW by entering a 1 in place of 4 (3)

**SYSTEM INFO**

Modify the inputs below to run the simulation.

DC System Size (kW):  3

and proceed to the next screen (4) to get system results

The results screen will tell you how many kWh/year to expect per 1 kW<sub>DC</sub> :

**1,372 kWh/Year\***  
System output may range from 1,327 to 1,434 kWh per year near this location. Click [HERE](#) for more information.

- (B) Using the kWh/year per kW<sub>DC</sub> can now be used to determine the system size in kW<sub>DC</sub> based on your annual kWh you determined with your monthly utility bills as shown in column D rows 4 (annual kWh) and column D row 7 (system size in kW<sub>DC</sub>). Note that you can overwrite the kWh/year in column D row 3 as your solar installer may have a different estimate based on the system they are installing (Note the range in results from the website). Altering electricity generated per year affects system size and thereby cost of installation.
- (C) You can also specify additional capacity for the system if you expect your electricity needs to increase over time. Net metering (selling electricity to the grid applies only to the amount you plan to use from the grid and solar panels do not directly supply to your energy need). The solar panels deliver energy to the inverter, which converts DC to AC and supplies the electricity to the grid such that the grid acts as the battery for your farm operation. If you size your system too large (supplying more energy to the grid than what you use), the electric company may not reimburse at the rate at which you buy from the grid. Instead, excess electricity may be reimbursed from the grid at a lower rate. Once system size is determined, you can opt to employ tracker system technology such that solar panels follow the sun's orbit to create more kWh/year. Such systems are typically larger than 500 kW<sub>DC</sub>. Turning on tracker technology now uses kWh/year as shown column F row 3 and column D row 3 fades away.
- (D) Initial cost is based on sliding cost scale based on system size. Included are system installation and electric system upgrade costs. The estimated cost of the system is thus based on \$1.70 per kW<sub>DC</sub> for systems up to 199 kW<sub>DC</sub>, a cost of \$1.61 per kW<sub>DC</sub> for systems from 200 – 499 kW<sub>DC</sub>, a cost of \$1.51 per kW<sub>DC</sub> from 500 – 999 kW<sub>DC</sub>, a cost of \$1.35 per kW<sub>DC</sub> for 1MW systems, with further cost breaks to \$1.25 per kW<sub>DC</sub> for 20 MW systems.
- (E) You can specify financing terms in this section. You can use your mouse to highlight extra information provided in places with red triangles.
- (F) Bonus depreciation allows the operation to depreciate the entire initial cost if the system went into service in 2022. By 2023, bonus depreciation is limited to 80% of the initial cost with the remainder depreciable using a 5-yr MACRS schedule or straight-line depreciation. The bonus depreciation declines by 20% in 2024, 2025 and 2026. The tool assumes the same rules for state income tax calculations (please consult with your accountant). The [website](#) link on the prior page provides an illustrative example.

Specifying Panel Productivity, System Expansion, Financing Terms, Use of Tracker Technology, Depreciation method, Electricity rate, Inflation, Federal and State Income Tax rates, Time to realize the federal income tax credit and Opportunity cost of Capital (cont'd)

PSA POULTRY SOLAR ANALYSIS

Reset Refresh

Monthly Bills

Notes: See notes for items (A) through (F) on p. 2

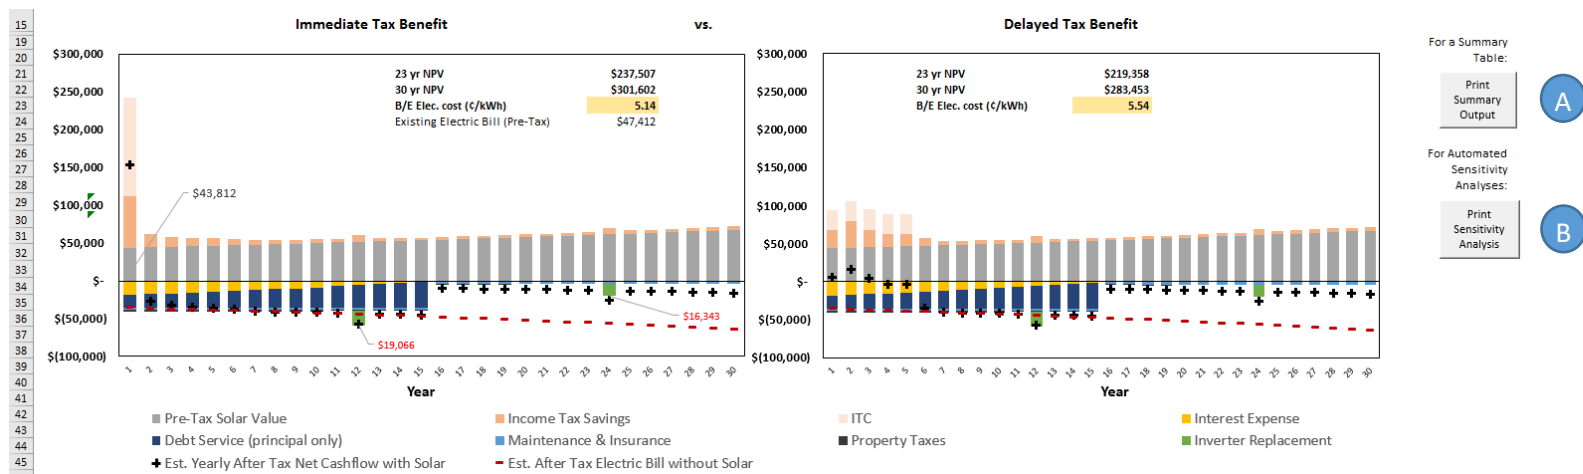

(G) You can modify the electricity rate as estimated by the computer from p. 1 (accessible by clicking on the "Monthly Bills" arrow or column R row 2 on that screen) to use both a modified access fee (p. 1 item D) and a different variable electricity rate. Clicking on the "Reset" button reestablishes the link to the computer estimate from the prior page.

(H) While inflation is high in 2022, such expectations hopefully will not persist over the next 30 years. An electricity inflation rate between 1 and 3 percent per year is suggested. By the same token, inflation for Operations and

Maintenance (O & M) are expected to be minimal as new technology becomes available (i.e. new inverters). The monthly base fee for access fees, demand charges, and other electric utility company costs that are expected to prevail with a solar system installation can be modified using the prior input screen (p. 1).

- (I) Please consult with your accountant to determine an appropriate federal and state income tax rate. The same rate is applied over the 30 year investment horizon associated with the solar system.
- (J) The federal income tax credit has a 3 year carry back and 22 year carry forward period per latest [federal rules](#). As such, pending taxable income, you may need more than 1 year to reap tax benefits associated with bonus depreciation and income tax credits. Column J row 12 allows you to spread tax benefits over a longer time period. Note that this tool eliminates bonus depreciation for delayed realization of tax benefits as the graphs (not shown for space reasons here) are expected to provide the user with a range of cashflow repercussions that hinge in part on how fast tax benefits can be realized.
- (K) The tool allows use of 5-yr Modified Accelerated Cost Recovery (MACRS) which depreciates the solar system for tax purposes over the course of 6 years (with or without bonus depreciation considerations pending on time chosen to realized income tax credit benefits). You can also specify straight line depreciation (SLN) which applies the same level of annual depreciation over the useful life of the system. You can specify the useful life in column J row 4. Using either MACRS or SLN, the salvage value of the system is zero. Property taxes on the solar installation are assessed based on the useful life specified in column J row 4 using straight line depreciation even when MACRS is chosen.
- (L) The discount rate chosen accounts for time value of money and risk. Choosing a higher discount rate assumes you think of the investment as risky and vice versa with a lower discount rate. Since cashflows before and after solar installation and different income tax benefit realization periods occur over a period of 30 years, we discount all future cashflows using the discount rate to reflect the financial impact over the 30-year period in today's dollars as shown on the next page (p. 4).

## Comparing Cashflows on the Basis of Time to Realize Income Tax Credits and in Relation to Current Electricity Bill Information

Note: The graphs above continuously update with changes to financing terms, system size, use of track technology and other system parameters discussed on p. 1-3. On the left is a cashflow scenario where all income tax benefits are realized in the first year whereas the graph on the right showcases cashflow implications with delayed realization of income tax benefits. A tabular presentation of these cashflows can be printed as a pdf file or a printer of your choosing by clicking on the “Print Summary Output” button **(A)**. The red minus signs on the graphs indicate the current state of affairs with solar investment. They represent the *after tax* cost of electricity using the electricity rate and base fee assumptions as explained above (p.1-2). The black plus signs represent *after-tax* cashflows with the solar panel investment. They summarize income tax benefits of the federal income tax credit and bonus depreciation (if all can be realized in year 1) and sales of solar energy to the grid at the variable electricity rate specified. Subtracted are principal and interest payments on the loan, operating and maintenance charges, the cost to replace the inverter(s) in years 12 and 24, and property taxes. To make the system installation profitable, the + signs need to be above the – signs. In general, that occurs early when realizing accelerated depreciation benefits and income tax credits and again once the loan is paid off. The net effect of the difference in cashflow between the +’s and –’s is summarized across 23 and 30 years in the graph in rows 21 and 22, respectively, and labeled as the 23 yr NPV and 30 yr NPV. Those two numbers reflect the net cashflow effect of investing in solar panels up to year 23 (before the second inverter replacement) and over the entire 30 years. The B/E Elec. Cost in cents per kWh, in row 23, is the cost of electricity with the solar system to compare to the electricity rate in the like-shaded box in column J row 6 or item G on p. 3 of this user guide. So the user hopes to have positive NPV numbers, the larger the better, and low B/E Elec. cost for the investment to be beneficial. Even if positive NPV can be achieved and the B/E Elec. Cost is low, the decision maker needs to take the impact of borrowing money (as specified on p. 2 in section E) into account. The investment amount can tie up substantial borrowing capacity. A REAP grant may help as a down payment and would add to NPV and lower B/E Elec. cost further. Since a large number of parameters can be changed above the graphs, an **automated sensitivity analysis can be performed (B)** by clicking on the “Print Sensitivity Analysis” button. Generating that 1-page report **takes a couple of minutes and leads to unavoidable screen flickering**. The output can be directed to a printer of your choice or printed as a pdf file. The sensitivity analyses reflect on loan length, amount financed, use of tracker technology, interest rate on the loan, changes in electricity inflation rate, alternative base fees, and time period to realize income tax benefits. Outcomes are summarized using NPV and B/E cost information. Sample reports are attached below.

**Summary of Output with Current Selections on  
Interest Rate, Amount Financed, etc.**

30 yr NPV:		\$301,602	<b>IMMEDIATE TAX BENEFIT WITH ALL BONUS DEPRECIATION REALIZED</b>

NOTE: Sensitivity analyses are in comparison to a loan length of 15 years @5%, with 85% of purchase cost financed, without tracker technology, expected electricity inflation of 2%, O&M inflation of 1%, a base fee of \$300.00/month, and Fed. and State Income tax rates of 20 and 5%, respectively. Install Year is 2024 and you are using 30% Federal Income Tax Credit (2023 through 2033).
